N-SULFONYLPIPERIDINES AS METALLOPROTEINASE INHIBITORS (TACE)

The present invention relates to compounds useful in the inhibition of metalloproteinases and in particular to pharmaceutical compositions comprising them, as well as their use.

The compounds of this invention are inhibitors of one or more metalloproteinase enzymes and are particularly effective as inhibitors of TACE (TNFα Converting Enzyme). Metalloproteinases are a superfamily of proteinases (enzymes) whose numbers in recent years have increased dramatically. Based on structural and functional considerations these enzymes have been classified into families and subfamilies as described in N.M. Hooper (1994) FEBS Letters 354:1-6. Examples of metalloproteinases include the matrix metalloproteinases (MMP) such as the collagenases (MMP1, MMP8, MMP13), the gelatinases (MMP2, MMP9), the stromelysins (MMP3, MMP10, MMP11), matrilysin (MMP7), metalloelastase (MMP12), enamelysin (MMP19), the MT-MMPs (MMP14, MMP15, MMP16, MMP17); the reprolysin or adamalysin or MDC family which includes the secretases and sheddases such as TNF converting enzymes (ADAM10 and TACE); the astacin family which include enzymes such as procollagen processing proteinase (PCP); and other metalloproteinases such as aggrecanase, the endothelin converting enzyme family and the angiotensin converting enzyme family.

Metalloproteinases are believed to be important in a plethora of physiological disease processes that involve tissue remodelling such as embryonic development, bone formation and uterine remodelling during menstruation. This is based on the ability of the metalloproteinases to cleave a broad range of matrix substrates such as collagen, proteoglycan and fibronectin. Metalloproteinases are also believed to be important in the processing, or secretion, of biologically important cell mediators, such as tumour necrosis factor (TNF); and the post translational proteolysis processing, or shedding, of biologically important membrane proteins, such as the low affinity IgE receptor CD23 (for a more complete list see N. M. Hooper *et al.*, (1997) Biochem J. 321:265-279).

Metalloproteinases have been associated with many disease conditions. Inhibition of the activity of one or more metalloproteinases may well be of benefit in these disease conditions, for example: various inflammatory and allergic diseases such as, inflammation of the joint (especially rheumatoid arthritis, osteoarthritis and gout), inflammation of the gastro-

intestinal tract (especially inflammatory bowel disease, ulcerative colitis and gastritis), inflammation of the skin (especially psoriasis, eczema and dermatitis); in tumour metastasis or invasion; in disease associated with uncontrolled degradation of the extracellular matrix such as osteoarthritis; in bone resorptive disease (such as osteoporosis and Paget's disease)); in diseases associated with aberrant angiogenesis; the enhanced collagen remodelling associated with diabetes, periodontal disease (such as gingivitis), corneal ulceration, ulceration of the skin, post-operative conditions (such as colonic anastomosis) and dermal wound healing; demyelinating diseases of the central and peripheral nervous systems (such as multiple sclerosis); Alzheimer's disease; and extracellular matrix remodelling observed in cardiovascular diseases such as restenosis and atheroscelerosis.

A number of metalloproteinase inhibitors are known; different classes of compounds may have different degrees of potency and selectivity for inhibiting various metalloproteinases. We have discovered a class of compounds that are inhibitors of metalloproteinases and are of particular interest in inhibiting TACE. The compounds of this invention have beneficial potency and/or pharmacokinetic properties.

TACE (also known as ADAM17) which has been isolated and cloned [R.A. Black *et al.* (1997) Nature 385:729-733; M.L. Moss *et al.* (1997) Nature 385:733-736] is a member of the admalysin family of metalloproteins. TACE has been shown to be responsible for the cleavage of pro-TNFα, a 26kDa membrane bound protein to release 17kDa biologically active soluble TNFα [Schlondorff *et al.* (2000) Biochem. J. 347: 131-138]. TACE mRNA is found in most tissues, however TNFα is produced primarily by activated monocytes, macrophages and T lymphocytes. TNFα has been implicated in a wide range of pro-inflammatory biological processes including induction of adhesion molecules and chemokines to promote cell trafficking, induction of matrix destroying enzymes, activation of fibroblasts to produce prostaglandins and activation of the immune system [Aggarwal *et al* (1996) Eur. Cytokine Netw. 7: 93-124]. Clinical use of the anti-TNF biologicals has shown TNFα to play an important role in a range of inflammatory diseases including rheumatoid arthritis, Crohn's disease and psoriasis [Onrust *et al* (1998) Biodrugs 10: 397-422, Jarvis et al (1999) Drugs 57:945-964]. TACE activity has also been implicated in the shedding of other membrane bound proteins including TGFα, p75 & p55 TNF receptors, L-selectin and amyloid precursor protein [Black (2002) Int. J. Biochem. Cell Biol. 34: 1-5]. The biology of TACE inhibition has recently been reviewed and shows TACE to have a central role in TNFα production and

selective TACE inhibitors to have equal, and possibly greater, efficacy in the collagen induced arthritis model of RA than strategies that directly neutralise TNFα [Newton et al (2001) Ann. Rheum. Dis. 60: iii25-iii32].

A TACE inhibitor might therefore be expected to show efficacy in all disease where TNFα has been implicated including, but not limited to, inflammatory diseases including rheumatoid arthritis and psoriasis, autoimmune diseases, allergic/atopic diseases, transplant rejection, graft versus host disease, cardiovascular disease, reperfusion injury and malignancy.

Compounds that inhibit matrix metalloproteinases are already known in the art. WO 00/12477 discloses hydroxamic acids and carboxylic acid derivatives that are inhibitors of matrix metalloproteinases; WO 00/12478 discloses arylpiperazines that are useful in the inhibition of matrix metalloproteinase and are of particular interest as regards the inhibition of MMP13 and MMP9; and WO 01/87870 discloses hydroxamic acid derivatives which are inhibitors of matrix metalloproteinases including ADAM or ADAM-TS enzymes.

Surprisingly we have discovered that a selection of compounds are very potent inhibitors of TACE (ADAM17) and are particularly noteworthy for their unexpected selectivity for TACE over the matrix metalloproteinases

Additionally further effective compounds are disclosed.

"Saturated heterocyclic 3 to 7-membered" rings are oxiranyl, aziridinyl, thiirane, azetidinyl, oxetanyl, thietanyl, tetrahydrothienyl, pyrrolidinyl, tetrahydrofuranyl, tetrahydro-2H-pyranyl, tetrahydro-2H-thiopyranyl and piperidinyl and a ring nitrogen may be substituted by a group selected from formyl, acetyl and mesyl.

A "carbocyclic 3 to 6-membered" ring is a saturated, partially saturated or unsaturated ring containing 3 to 6 ring carbon atoms. Examples include cyclopropyl, cyclobutyl, cyclopentyl, cyclopent-3-enyl, cyclohexyl and cyclopent-2-enyl.

Where optional substituents are chosen from "one of more" groups or substituents it is to be understood that this definition includes all substituents being chosen from one of the specified groups or the substituents being chosen from two or more of the specified groups.

Preferably "one or more" means "1, 2 or 3" and this is particularly the case when the group or substituent is halo. "One or more" may also means "1 or 2".

formula (20) include sodium hydride, lithium diisopropylamide, butyllithium and lithium bis(trimethylsilyl)amide; suitable reaction conditions for a) are temperatures ranging from –78°C to 70°C and an aprotic solvent, e.g. tetrahydrofuran under argon; suitable protecting groups (PG) include Boc (t-butoxycarbonyl), CBz (carbonyloxybenzyl) groups and mesyl or another alkylsulphonyl. In the case where PG is alkylsulphonyl, reaction of formula (16) and (17) and of formula (20) and formula (21) directly produces a compound of formula (4). A compound of formula (18) can be converted to formula (19) by treatment with acid (Boc) or hydrogen/ palladium (CBz). A compound of formula (19) can be converted to a compound of formula (4) by treatment with an alkylsulfonylchloride in the presence of a base such as pyridine in a solvent such as dichloromethane. In the case where t=0, Q is O, L is OH and B is aromatic, Mitsunobu conditions can be used to form a compound of formula (18), i.e. a compound of formula (16) or formula (20) would be reacted with a mixture of diethyl azodicarboxylate or diisopropylazodicarboxylate and triphenylphosphine and a compound of formula (17) or formula (21) to give a compound of formula (4). In addition PG could also be a protected hydroxamic acid or reverse hydroxamate. Thus reaction of formula (16) and (17) and of formula (20) and (21) would deliver a protected version of formula (1) which could then be deprotected.

A compound of formula (1) can be prepared by removal of a protecting group on the zinc binding group directly. The protecting group (PG) can be benzyl or 2,4-dimethoxybenzyl. The former can be removed by treatment with hydrogen/ palladium and the latter by treatment with mild acid (see Tetrahedron Letters, 1998, 39(43), 7865). The required protected hydroxamic acid or reverse hydroxamate can be obtained by using a suitably protected hydroxylamine earlier in the synthesis.

It will also be appreciated that in some of the reactions mentioned herein it may be necessary/desirable to protect any sensitive groups in the compounds. The instances where protection is necessary or desirable and suitable methods for protection are known to those skilled in the art. Conventional protecting groups may be used in accordance with standard practice (for illustration see T.W. Green, Protective Groups in Organic Synthesis, John Wiley and Sons, 1991). Thus, if reactants include groups such as amino, carboxy or hydroxy it may be desirable to protect the group in some of the reactions mentioned herein.

A suitable protecting group for an amino or alkylamino group is, for example, an acyl group, for example an alkanoyl group such as acetyl, an alkoxycarbonyl group, for example a methoxycarbonyl, ethoxycarbonyl or *t*-butoxycarbonyl group, an arylmethoxycarbonyl group,

for example benzyloxycarbonyl, or an aroyl group, for example benzoyl. The deprotection conditions for the above protecting groups necessarily vary with the choice of protecting group. Thus, for example, an acyl group such as an alkanoyl or alkoxycarbonyl group or an aroyl group may be removed for example, by hydrolysis with a suitable base such as an alkali metal hydroxide, for example lithium or sodium hydroxide. Alternatively an acyl group such as a *t*-butoxycarbonyl group may be removed, for example, by treatment with a suitable acid such as hydrochloric, sulphuric or phosphoric acid or trifluoroacetic acid and an arylmethoxycarbonyl group such as a benzyloxycarbonyl group may be removed, for example, by hydrogenation over a catalyst such as palladium-on-carbon, or by treatment with a Lewis acid for example boron tris(trifluoroacetate). A suitable alternative protecting group for a primary amino group is, for example, a phthaloyl group which may be removed by treatment with an alkylamine, for example dimethylaminopropylamine, or with hydrazine.

A suitable protecting group for a hydroxy group is, for example, an acyl group, for example an alkanoyl group such as acetyl, an aroyl group, for example benzoyl, or an arylmethyl group, for example benzyl. The deprotection conditions for the above protecting groups will necessarily vary with the choice of protecting group. Thus, for example, an acyl group such as an alkanoyl or an aroyl group may be removed, for example, by hydrolysis with a suitable base such as an alkali metal hydroxide, for example lithium or sodium hydroxide. Alternatively an arylmethyl group such as a benzyl group may be removed, for example, by hydrogenation over a catalyst such as palladium-on-carbon.

A suitable protecting group for a carboxy group is, for example, an esterifying group, for example a methyl or an ethyl group which may be removed, for example, by hydrolysis with a base such as sodium hydroxide, or for example a *tert*-butyl group which may be removed, for example, by treatment with an acid, for example an organic acid such as trifluoroacetic acid, or for example a benzyl group which may be removed, for example, by hydrogenation over a catalyst such as palladium-on-carbon.

The protecting groups may be removed at any convenient stage in the synthesis using conventional techniques well known in the chemical art.

As stated hereinbefore the compounds defined in the present invention possesses metalloproteinases inhibitory activity, and in particular TACE inhibitory activity. This property may be assessed, for example, using the procedure set out below.

Isolated Enzyme Assays

Matrix Metalloproteinase family including for example MMP13.

Recombinant human proMMP13 may be expressed and purified as described by Knauper *et al.* [V. Knauper *et al.*, (1996) The Biochemical Journal 271:1544-1550 (1996)]. The purified enzyme can be used to monitor inhibitors of activity as follows: purified proMMP13 is activated using 1mM amino phenyl mercuric acid (APMA), 20 hours at 21°C; the activated MMP13 (11.25ng per assay) is incubated for 4-5 hours at 35°C in assay buffer (0.1M Tris-HCl, pH 7.5 containing 0.1M NaCl, 20mM $CaCl_2$, 0.02 mM ZnCl and 0.05% (w/v) Brij 35 using the synthetic substrate 7-methoxycoumarin-4-yl)acetyl.Pro.Leu.Gly.Leu.N-3-(2,4-dinitrophenyl)-L-2,3-diaminopropionyl.Ala.Arg.NH_2 in the presence or absence of inhibitors. Activity is determined by measuring the fluorescence at λex 328nm and λem 393nm. Percent inhibition is calculated as follows: % Inhibition is equal to the [$Fluorescence_{plus\ inhibitor}$ - $Fluorescence_{background}$] divided by the [$Fluorescence_{minus\ inhibitor}$ - $Fluorescence_{background}$].

A similar protocol can be used for other expressed and purified pro MMPs using substrates and buffers conditions optimal for the particular MMP, for instance as described in C. Graham Knight *et al.*, (1992) FEBS Lett. 296(3):263-266.

Adamalysin family including for example TNF convertase

The ability of the compounds to inhibit proTNFα convertase enzyme (TACE) may be assessed using a partially purified, isolated enzyme assay, the enzyme being obtained from the membranes of THP-1 as described by K. M. Mohler *et al.*, (1994) Nature 370:218-220. The purified enzyme activity and inhibition thereof is determined by incubating the partially purified enzyme in the presence or absence of test compounds using the substrate 4',5'-Dimethoxy-fluoresceinyl Ser.Pro.Leu.Ala.Gln.Ala.Val.Arg.Ser.Ser.Ser.Arg.Cys(4-(3-succinimid-1-yl)-fluorescein)-NH_2 in assay buffer (50mM Tris HCl, pH 7.4 containing 0.1% (w/v) Triton X-100 and 2mM $CaCl_2$), at 26°C for 4 hours. The amount of inhibition is determined as for MMP13 except λex 485nm and λem 538nm were used. The substrate was synthesised as follows. The peptidic part of the substrate was assembled on Fmoc-NH-Rink-MBHA-polystyrene resin either manually or on an automated peptide synthesiser by standard methods involving the use of Fmoc-amino acids and O-benzotriazol-1-yl-N,N,N',N'-tetramethyluronium hexafluorophosphate (HBTU) as coupling agent with at least a 4- or 5-

fold excess of Fmoc-amino acid and HBTU. Ser^1 and Pro^2 were double-coupled. The following side chain protection strategy was employed; Ser^1(But), Gln^5(Trityl), $Arg^{8,12}$(Pmc or Pbf), $Ser^{9,10,11}$(Trityl), Cys^{13}(Trityl). Following assembly, the N-terminal Fmoc-protecting group was removed by treating the Fmoc-peptidyl-resin with in DMF. The amino-peptidyl-resin so obtained was acylated by treatment for 1.5-2hours at 70°C with 1.5-2 equivalents of 4',5'-dimethoxy-fluorescein-4(5)-carboxylic acid [Khanna & Ullman, (1980) Anal Biochem. 108:156-161) which had been preactivated with diisopropylcarbodiimide and 1-hydroxybenzotriazole in DMF]. The dimethoxyfluoresceinyl-peptide was then simultaneously deprotected and cleaved from the resin by treatment with trifluoroacetic acid containing 5% each of water and triethylsilane. The dimethoxyfluoresceinyl-peptide was isolated by evaporation, trituration with diethyl ether and filtration. The isolated peptide was reacted with 4-(N-maleimido)-fluorescein in DMF containing diisopropylethylamine, the product purified by RP-HPLC and finally isolated by freeze-drying from aqueous acetic acid. The product was characterised by MALDI-TOF MS and amino acid analysis.

The compounds of the invention have been found to be active against TACE at 0.1nM to 50μM, and in particular 10μM of compound 25 gave 97% inhibition and 10μM of compound 42 gave 99% inhibition.

Natural Substrates

The activity of the compounds of the invention as inhibitors of aggrecan degradation may be assayed using methods for example based on the disclosures of E. C. Arner *et al.*, (1998) Osteoarthritis and Cartilage 6:214-228; (1999) Journal of Biological Chemistry, 274 (10), 6594-6601 and the antibodies described therein. The potency of compounds to act as inhibitors against collagenases can be determined as described by T. Cawston and A. Barrett (1979) Anal. Biochem. 99:340-345.

The ability of the compounds of this invention to inhibit the cellular processing of TNFα production may be assessed in THP-1 cells using an ELISA to detect released TNF essentially as described K. M. Mohler *et al.*, (1994) Nature 370:218-220. In a similar fashion the processing or shedding of other membrane molecules such as those described in N. M.

Hooper *et al.*, (1997) Biochem. J. 321:265-279 may be tested using appropriate cell lines and with suitable antibodies to detect the shed protein.

Test as an agent to inhibit cell based invasion

The ability of the compound of this invention to inhibit the migration of cells in an invasion assay may be determined as described in A. Albini *et al.*, (1987) Cancer Research 47:3239-3245.

Test as an agent to inhibit whole blood TNF sheddase activity

The ability of the compounds of this invention to inhibit TNFα production is assessed in a human whole blood assay where LPS is used to stimulate the release of TNFα. 160μl of heparinized (10Units/ml) human blood obtained from volunteers, was added to the plate and incubated with 20μl of test compound (duplicates), in RPMI1640 + bicarbonate, penicillin, streptomycin, glutamine and 1% DMSO, for 30 minutes at 37°C in a humidified ($5\%CO_2/95\%$air) incubator, prior to addition of 20μl LPS (E. coli. 0111:B4; final concentration 10μg/ml). Each assay includes controls of neat blood incubated with medium alone or LPS (6 wells/plate of each). The plates are then incubated for 6 hours at 37°C (humidified incubator), centrifuged (2000rpm for 10 min; 4°C), plasma harvested (50-100μl) and stored in 96 well plates at -70°C before subsequent analysis for TNFα concentration by ELISA.

Test as an agent to inhibit in vitro cartilage degradation

The ability of the compounds of this invention to inhibit the degradation of the aggrecan or collagen components of cartilage can be assessed essentially as described by K. M. Bottomley *et al.*, (1997) Biochem J. 323:483-488.

In vivo assessment

Test as an anti-TNF agent

The ability of the compounds of this invention as *in vivo* TNFα inhibitors is assessed in the rat. Briefly, groups of female Wistar Alderley Park (AP) rats (90-100g) are dosed with compound (5 rats) or drug vehicle (5 rats) by the appropriate route e.g. peroral (p.o.), intraperitoneal (i.p.), subcutaneous (s.c.) 1 hour prior to lipopolysaccharide (LPS) challenge (30μg/rat i.v.). Sixty minutes following LPS challenge rats are anaesthetised and a terminal blood sample taken via the posterior vena cavae. Blood is allowed to clot at room temperature

for 2hours and serum samples obtained. These are stored at –20°C for TNFα ELISA and compound concentration analysis.

Data analysis by dedicated software calculates for each compound/dose:

Percent inhibition of TNFα= Mean TNFα (Vehicle control) – Mean TNFα (Treated) X 100

Mean TNFα (Vehicle control)

Test as an anti-arthritic agent

Activity of a compound as an anti-arthritic is tested in the collagen-induced arthritis (CIA) as defined by D. E. Trentham *et al.*, (1977) J. Exp. Med. 146,:857. In this model acid soluble native type II collagen causes polyarthritis in rats when administered in Freunds incomplete adjuvant. Similar conditions can be used to induce arthritis in mice and primates.

MS: 455.

The starting (R/S)-2-{[4-[(2,5-difluorobenzyl)oxy]piperidin-1-yl]sulphonyl}-1-phenylethylhydroxylamine was prepared as follows:

i) Triethylamine (8.0g, 0.079mol) was added to a stirred solution of *E*-β-styrenesulphonyl chloride (12.0g, 0.059mol) and 4-hydroxypiperidine (8.0g, 0.079mol) in THF (100ml) at RT. Stirring was continued overnight before the reaction mixture was concentrated to low volume and partitioned between EtOAc followed by aqueous 1M HCl, saturated sodium hydrogen carbonate and brine. The organic fraction was then dried (Na_2SO_4) and concentrated to give E-1-[4-hydroxypiperidin-1-ylsulphonyl]-2-phenylethene. (12.75g; 0.046mol); NMR ($CDCl_3$): 1.5–1.8 (m, 4H), 1.9–2.1 (m, 2H), 3.0–3.2 (m, 2H), 3.4–3.6 (m, 2H), 3.85 (s, 1H), 6.65 (s, 1H) and 7.3–7.6 (m, 6H); MS: 268.

ii) E-1-[4-hydroxypiperidin-1-ylsulphonyl]-2-phenylethene was dissolved in DMF (0.2g; 0.75mmol in 3ml) and 2,5-difluorobenzyl bromide (1.5mmol) was added. A covering of

argon gas was introduced before solid sodium hydride (0.1g; incl. oil) was carefully added, in three portions to the stirred reaction. Stirring was continued overnight. Water (5ml) was added (dropwise initially) and the resultant mixture extracted with EtOAc (5ml). The organic layer was separated and the aqueous layer washed again with EtOAc (3ml). The combined organics were evaporated, re-dissolved in DCM (5ml) and applied to a 10g Silica BondElut column and eluted with a gradient from DCM to 2.5% MeOH in DCM to give E-1-[4-[(2,5-difluorobenzyl)oxy]piperidin-1-ylsulphonyl]-2-phenylethene which was carried through to the next step.

iii) E-1-[4-[(2,5-difluorobenzyl)oxy]piperidin-1-ylsulphonyl]-2-phenylethene, was dissolved in THF (1ml) and the air in the tube excluded with argon before hydroxylamine in water (50% solution, 1ml) was added and the mixture stirred vigorously overnight. EtOAc (1ml) was added and the aqueous layer separated. The organic layers were washed with brine and dried (Na_2SO_4) and concentrated to give (R/S)-2-{[4-[(2,5-difluorobenzyl)oxy]piperidin-1-yl]sulphonyl}-1-phenylethylhydroxylamine which was carried through to the final step.

EXAMPLES 32-45

The procedure described in Example 13 was repeated using the appropriate halide (bromo or chloro) in place of 2,5-difluorobenzyl bromide and using *E*-1-[4-hydroxypiperidin-1-ylsulphonyl]-2-(pyrid-3-yl)ethene (described below) instead of *E*-1-[4-hydroxypiperidin-1-ylsulphonyl]-2-phenylethene to give the products listed.

The synthesis of the starting *E*-1-[4-hydroxypiperidin-1-ylsulphonyl]-2-(pyrid-3-yl)ethene is shown below:

i) A solution of 4-hydroxypiperidine (8g; 0.08mol) in DCM (80ml) was cooled in an ice bath before pyridine (7.4ml; 0.09mol) and TBDMS triflate (20ml; 0.088mol) were added. The resulting mixture was stirred for 2.5 hours. Iced water was added and the organic layer separated, washed with brine, dried and evaporated to give 4-(*tert*-butyldimethylsilyl)oxypiperidine as a pale yellow residue (24g).

ii) Methanesulphonyl chloride (1.0ml; 0.012mol) was added to a solution of the 4-(*tert*-butyldimethylsilyl)oxypiperidine (2.7g; 0.012mol) and DIPEA (4.4ml; 0.025mol) in DCM (20ml) and the whole stirred at RT overnight. Water (20ml) was added and the organic layer separated and washed with 2M hydrochloric acid, saturated sodium bicarbonate and brine and evaporated to give 1-methanesulphonyl-4-(*tert*-butyldimethylsilyl)oxypiperidine as a black, oily residue.

iii) A solution of 1-methanesulphonyl-4-(*tert*-butyldimethylsilyl)oxypiperidine (2.0g; 6.8mmol) in THF (50ml) was covered with argon and cooled in an ice/ acetone bath before a solution of LHMDS in THF (15.0ml; 1M; 15.0mmol) was added dropwise. After stirring for 30 minutes, diethyl chlorophosphate (1.0ml; 6.8mmol) was added and stirring continued for a further 50 minutes. Nicotinaldehyde (0.64ml; 6.8mmol) was then added and the solution allowed to warm to RT and stirred overnight. A saturated solution of ammonium chloride was then added and the mixture extracted with EtOAc. The dried organic extracts were concentrated in vacuo. Purification was by chromatography on silica, eluting with a increasing gradient from hexane to 50% EtOAc in hexane to give *E*-1-[4-(*tert*-butyldimethylsilyloxy)piperidin-1-ylsulphonyl]-2-(pyrid-3-yl)ethene (1.93g, 5.05mmol).

iv) *E*-1-[4-(*tert*-butyldimethylsilyloxy)piperidin-1-ylsulphonyl]-2-(pyrid-3-yl)ethene (1.93g; 5.05mmol) was added to a preformed-mixture of acetyl chloride (2ml) in MeOH (20ml) and stirred at RT for 2 hours. Concentration in vacuo gave a solid which was

partitioned between saturated sodium bicarbonate and EtOAc. The organic extracts were dried and evaporated. Purification was by chromatography on silica (20g) eluting with a gradient from DCM to 20% MeOH in DCM. Evaporation of fractions containing product gave *E*-1-[4-(hydroxy)piperidin-1-ylsulphonyl]-2-(pyrid-3-yl)ethene as a white solid (0.4g; 30%). NMR (400MHz): d, 1.4 (2H, m, CH2); 1.8 (2H, m, CH_2); 2.9 (2H, m, CH_2); 3.2 (2H, m, CH_2); 3.6 (1H, m, CH); 4.8 (1H, d, OH); 7.5 (3H, m, CH); 8.2 (1H, m, CH); 8.6 (1H, m, CH); 8.9 (1H, d, CH).
